Other Information 27
1 Introduction

1.1 Overview
This document aims to provide a standardised view on how 5G System (5GS) networks making use of the 5G Core (5GC) can interconnect and/or interwork when users roam onto a network different to their HPMN (Home Public Mobile Network). This will be applicable when NR (New Radio) or eLTE (evolved LTE) radio bearers are used, connected to a 5GC, and both UE (user equipment) and VPMN (visited PMN) have matching capabilities. The main focus is to describe 5GC and NR.

References will be made to 3GPP specifications covering the 5GS, as well as other GSMA NG PRD’s, such as GSMA PRD IR.88 [3] where EPC (Evolved Packet Core) interworking is specified for roaming purposes, using E-UTRAN (LTE only or LTE and 5G NR bearers).

1.2 Scope
This PRD presents material about 5GS Roaming where the 5GC using the SBA (Service Based Architecture) is used by the HPMN and the VPMN. The document addresses aspects that are new for 5GS roaming in general, using NR mainly, but also 5GS architectures where 4G E-UTRA is used.

* in scope of this PRD
** in GSMA PRD IR.88 [3]

# 5GC supports interworking with EPC as per 3GPP TS 23.501 [1] Section 4.3

The PRD describes the N32 interface between the HPMN and VPMN, and the services that are carried over it, as illustrated in the Architecture Model Interfaces (Section 2.2.)

This PRD is not covering Voice and SMS (Short Message Service) services; as these are described in GSMA PRD NG.114 [20].

Note: This version of the PRD only covers 5GS roaming over 3GPP (3rd Generation Partnership Project) access, NR and E-UTRAN attached to 5GC. WLAN access to 5GC will be covered in GSMA PRD NG.115 [30].

### Acronym | Description
--- | ---
PCF | Policy Control Function
PDU | Protocol Data Unit
PEI | Permanent Equipment Identifier
PGW | PDN (Packet Data Network) Gateway
PKI | Public Key Infrastructure
PLMN | Public Land Mobile Network
PMIP | Proxy Mobile IP
PRD | Permanent Reference Document
QCI | QoS Class Identifier
QoS | Quality of Service
RAN | Radio Access Network
RAT | Radio Access Technology
SA NR | Standalone New Radio
SBA | Service Based Architecture
SBI | Service Based Interface (5G)
SEPP | Security Edge Protection Proxy
SMF | Session Management Function
S- NSSAI | Single Network Slice Selection Assistance Information
SGW | Serving Gateway
SUCI | Subscription Concealed Identifier
SUPI | Subscriber Permanent Identifier
TA | Tracking Area
TAU | Tracking Area Update
TLS | Transport Layer Security
UDM | Unified Data Management
UDR | Unified Data Repository
UE | User Equipment
UPF | User Plane Function
USIM | Universal Subscriber Identity Module
VPMN | Visited Public Mobile Network
XCAP | XML Configuration Access Protocol
XML | eXtensible Markup Language
YAML | YAML Ain't Markup Language

2.3 Conventions

“The key words “must”, “must not”, “required”, “shall”, “shall not”, “should”, “should not”, “recommended”, “may”, and “optional” in this document are to be interpreted as described in RFC 2119 Error! Reference source not found..”
3 Architecture

3.1 Architecture Models

The following diagrams are produced based on the roaming reference architectures found in 3GPP TS 23.501 [1] covering:

- **5G System Roaming architecture – Local Breakout (LBO)**
  - Service Based Interface representation
  - Reference point representation
- **5G System Roaming architecture – Home Routed (HR)**
  - Service Based Interface representation
  - Reference point representation

Which of the Network Functions that are used by VPMN and HPMN depends on whether local-break out (LBO) or home-routed (HR) architecture are used, as depicted in the following figures.

Figure 1 5G System Roaming architecture – Service Based Interface Representation (LBO)
Figure 2 5G System Roaming architecture – Reference point Representation (LBO)

Figure 3 5G System Roaming architecture – Service Based Interface Representation (HR)
The SEPP (Security Edge Protection Proxy) is part of the roaming security architecture and described in section 6.5.2.

### 3.2 Roaming Interfaces

The following Inter-PLMN interfaces in Reference Point representation are relevant for 5GC roaming; and the associated services are defined by 3GPP as follows:

<table>
<thead>
<tr>
<th>Network Functions</th>
<th>Ref Point ID</th>
<th>Service Definition</th>
<th>Used for LBO, HR, or LBO &amp; HR</th>
</tr>
</thead>
<tbody>

**Figure 4 5G System Roaming architecture – Reference point Representation (HR)**
4 Technical Requirements and Recommendations for Interfaces

4.1 General requirements for Inter-PMN interfaces

Requirements relating to IP addressing and routing for PMN’s using the 5G Core and Service Based Architecture are addressed in this PRD. Where not specified in this PRD, the requirements for IP addressing and routing specified in GSMA PRD IR.33 [4], GSMA PRD IR.34 [5], GSMA PRD IR.40 [6], and GSMA PRD IR.67 [8] will apply.

The GRX/IPX (Global Roaming Exchange/Internet Packet Exchange) environment is considered as trusted, and is addressed in GSMA PRD IR.34 [5]. However, additional security functions will be specified in this PRD.

4.1.1 Transport Protocol – TCP / IP

The Transmission Control Protocol as described in IETF RFC 793 [23] shall be used as transport protocol for the HTTP/2 connection, as specified in 3GPP TS.23. 501 [1].

4.1.2 Serialization Protocol – JSON

The JavaScript Object Notation (JSON) format as described in IETF RFC 8259 [24] shall be used as serialization protocol, as specified in [1] for the Service Based Interfaces.

4.1.3 Interface Definition Language – OpenAPI

OpenAPI 3.0.0 [24] shall be used as the Interface Definition Language for the Service Based Interfaces.

4.1.4 Application Protocol – HTTP/2

HTTP/2 as described in IETF RFC 7540 [26] shall be used in the Service Based Interfaces. The Service Based Interfaces used in the 5G Core are further specified in 3GPP TS 29.500 [20].

Further detail on HTTP/2 routing across PLMNs can be found in 3GPP TS 29.500 [20].

Further detail on URI Structure can be found in TS.29.501, Section 4.4.

4.2 Inter PLMN (N32) Interface

The Inter-PLMN specification 3GPP TS 29.573 [10] has been produced by 3GPP to specify the protocol definitions and message flows, and also the APIs for the procedures on the PLMN (Public Land Mobile Network) interconnection interface (i.e. N32).

As stated in 3GPP TS 29.573 [10] the N32 interface is used between the SEPPs of a VPLMN and an HPLMN in roaming scenarios. Furthermore, 3GPP has specified N32 to be considered as two separate interfaces:

Note: The services will all traverse over the N32 interface between SEPP functions as specified by 3GPP TS 29.573 [10]. The N9 user-plane interface does not traverse between SEPP functions.

Table 1 Relevant inter-PMN interfaces for 5GC roaming
N32-c – Control Plane interface between the SEPPs for performing the initial handshake and negotiating the parameters to be applied for the actual N32 message forwarding. See section 4.2.2 of 3GPP TS 29.573 [10]

Figure 5 N32-c Interface

Once the initial HTTP/2 handshake is completed the N32-c connection is torn down. This connection is End-to-End between SEPPs and does not involve IPX to intercept the HTTP/2 connection; although the IPX may be involved for IP level routing.

N32-f – Forwarding interface between the SEPPs that is used for forwarding the communication between the Network Function (NF) service consumer and the NF service producer after applying application level security protection. See section 4.2.3 of 3GPP TS 29.573 [10].

Figure 6 N32-f Interface

N32-f can provide Application Level Security (ALS) as specified in 3GPP TS 33.501 [19] between SEPPs if negotiated using N32-c. ALS provides the following protection functionalities:

- Message protection of the information exchanged between NF service consumer and producer
- Forwarding of the application layer protected message from a SEPP in one PLMN to another PLMN by way of using IPX providers on the path. The IPX providers on the path may involve the insertion of content modification instructions which the receiving SEPP applies after verifying the integrity of such modification instructions.

The HTTP/2 connection used on N32-f is long lived; and when a SEPP establishes a connection towards another PLMN via IPX, the HTTP/2 connection from a SEPP terminates at the next hop IPX.

N32-f makes use of the HTTP/2 connection management requirements specified in 3GPP TS 29.500 [20]. Confidentiality protection shall apply to all IE’s for the N32-f JOSE protected message forwarding procedure, such that hop-by-hop security between SEPP and the IPXs should be established using an IPSec or TLS VPN.
If an IPX is not in the path between SEPPs, then an IPSec of Transport Layer Security, TLS VPN will be established directly.

Note: N32-f shall use “http” connections generated by a SEPP, and not “https”

### 4.2.1 IPX HTTP Proxy

The SEPP will act as a non-transparent Proxy for the NF’s when service based interfaces are used across PLMNs, however inside IPX service providers, an HTTP proxy may also be used to modify information elements (IE’s) inside the HTTP/2 request and response messages.

Acting in a similar manner to the IPX Diameter Proxy used in EPC roaming, the HTTP/2 Proxy can be used for inspection of messages, and modification of parameters.

Figure 7 illustrates the End to End HTTP/2 Service Based Architecture where HTTP Proxy functions are implemented by the PLMN and IPX.

![Figure 7 End to end HTTP/2 Roaming Architecture](image)

The SEPP in a PLMN shall contain operator-controlled policy that specifies which IE’s can be modified by the IPX provider directly related to the particular SEPP. For example, ‘SUPI, Subscriber Permanent Identifier’ or ‘location data’.

As stated in 3GPP TS 33.501 [19] - Each PLMN shall agree the modification policy with the IPX provider it has a relationship with prior to establishment of an N32 connection. Each modification policy applies to one individual relation between PLMN-operator and IPX provider. In order to cover the complete N32 connection both involved roaming partners shall exchange their modification policies. Both complementary modification policies shall comprise of the overall modification policy for this specific N32 connection.

Note: In order to validate modifications for messages received on the N32-f interface, the operator’s roaming partners will have to know the overall modification policy.

Note: Modification includes removal and addition of new IE. IEs therefore may not be present in the rewritten message.
The IEs that the IPX is allowed to modify shall be specified in a list giving an enumeration of JSON paths within the JSON object created by the SEPP. Wildcards may be used to specify paths.

This policy shall be specific per roaming partner and per IPX provider that is used for the specific roaming partner.

The modification policy shall reside in the SEPP.

For each roaming partner, the SEPP shall be able to store a policy for sending in addition to one for receiving.

The following basic validation rules shall always be applied irrespective of the policy exchanged between two roaming partners:

- IE’s requiring encryption shall not be inserted at a different location in the JSON object

4.3 N9 Interface between VPMN and HPMN UPF

The UPF (User Plane Function) selection methodology is specified in 3GPP TS 23.501 [1]. For the Local Break Out (LBO) deployment scenario, both the SMF (Session Management Function) and all UPF(s) for the PDU (Protocol Data Unit) Sessions are under the control of the VPLMN. The Home Routed (HR) scenario makes use of both SMF’s and UPF’s in the VPLMN and HPLMN. In this case the SMF in the HPLMN selects the UPF(s) in the HPLMN, and the SMF in the VPLMN selects the UPF(s) in the VPLMN. Thus, the N9 reference point for user plane traffic is only applicable to the HR scenario, as seen in Figures 3 & 4.

The use of a UPF in the VPLMN enables VPLMN charging, VPLMN LI and minimizes the impact on the HPLMN of the UE mobility within the VPLMN (e.g. for scenarios where SSC mode 1 applies).

Different simultaneous PDU Sessions from a UE may use different modes: Home Routed and LBO. The HPLMN can control via subscription data per DNN (Data Network Name) and per S-NSSAI (Single Network Slice Selection Assistance Information) whether a PDU Session is to be set-up in HR or in LBO mode.

4.3.1 Procedures

As noted in 3GPP TS 23.501 [1] - In the case of PDU Sessions per Home Routed deployment:

- NAS Session Management terminates in the SMF in VPLMN.
- The SMF in VPLMN forwards to the SMF in the HPLMN SM related information
- The SMF in the HPLMN receives the SUPI of the UE from the SMF in the VPLMN during the PDU Session Establishment procedure
- The SMF in HPLMN is responsible to check the UE request with regard to the user subscription and to possibly reject the UE request in the case of mismatch. The SMF in HPLMN obtains subscription data directly from the HPLMN UDM (Unified Data Management)
- The SMF in HPLMN may send QoS requirements associated with a PDU Session to the SMF in VPLMN. This may happen during the PDU Session Establishment
procedure and after the PDU Session is established. The interface between SMF in HPLMN and SMF in VPLMN is also able to carry (N9) User Plane forwarding information exchanged between SMF in HPLMN and SMF in VPLMN. The SMF in the VPLMN may check QoS requests from the SMF in HPLMN with respect to roaming agreements.

In the HR roaming case, the AMF (Access and Mobility Management Function) selects a SMF (Session Management Function) in the VPLMN and a SMF in the HPLMN as described in 3GPP TS 23.502 [2] clause 4.3.2.2.3.3, and provides the identifier of the selected SMF in the HPLMN to the selected SMF in the VPLMN.

Conversely, in roaming with LBO, the AMF selects a SMF in the VPLMN as described in 3GPP TS 23.502 [2] clause 4.3.2.2.3.2. In this case, when handling a PDU Session Establishment Request message, the SMF in the VPLMN may reject the N11 message (related with the PDU Session Establishment Request message) with a proper N11 cause. This triggers the AMF to select both a new SMF in the VPLMN and a SMF in the HPLMN in order to handle the PDU Session using home routed roaming.

4.3.2 GTP-U

The N9 interface makes use of GPRS Tunnelling Protocol, GTP version 1 for the User Plane. The UPF’s inside the PLMNs making use of the Home-Routed solution architecture will be compliant to 3GPP TS 29.281 [18] Rel-15.

5 Technical Requirements and Recommendations for Interworking and Co-Existence with E-UTRAN and EPC

5.1 Interworking scenarios

3GPP has specified interworking that allows 5GC network functions to support interfaces to an EPC. In particular, UDM+HSS (Home Subscriber Server) supports S6a, and SMF+PGW-C and UPF+PGWC support S8-C and S8-U respectively. The diagram shown in Figure 8 illustrates the Home-routed roaming architecture for interworking between 5GS EPC/E-UTRAN making use of the “EPC interfaces".
Figure 8 Home-routed roaming architecture for interworking between 5GS EPC/E-UTRAN

A 5GC in the HPMN that supports this interworking architecture, is therefore able to support 4G network roaming to an EPC based VPLMN. This type of EPC roaming will also be used initially when 5GC networks are deployed. EPC related functionality has to be supported in the Home PCF. This type of EPC roaming can be with and without ‘E-UTRAN New Radio – Dual Connectivity’ in the VPMN. See GSMA PRD IR.88 [3] for details.

Note: Support of split control and user plane functions in the VPLMN SGW is not required.

5.2 Co-existence scenarios

It is anticipated that both 5GS (using 5GC) roaming and LTE roaming using EPC, as well as 3G/2G roaming using a circuit switched and mobile packet core will be provided at the same time between two PMNs.

This section describes the roaming scenarios where 5GC is used and the UE supports the radio access technology and frequency band of the VPMN, 3G and 2G co-existence is outside of the scope of this PRD.

As stated in 3GPP TS.23.501 [1] Section 5.17, deployments based on different 3GPP architecture options (i.e. EPC based or 5GC based) and UEs with different capabilities (EPC NAS and 5GC NAS) may coexist at the same time within one PLMN

It is assumed that a UE that is capable of supporting 5GC NAS procedures may also be capable of supporting EPC NAS (i.e. the NAS procedures defined in 3GPP TS 24.301) to operate in legacy EPC networks when roaming.
5.3 Inter-RAT Handover

Handover attempts to NR connected to 5GC from 4G LTE will occur, with active data sessions at risk of disruption under the condition that a roaming agreement exists for 4G, but not for 5G between PMN’s. The MME can prevent such handover attempts by including RAT and Core Network Type restrictions in the Handover Restriction List to E-UTRAN (see also section Error! Reference source not found.). There is also the possibility that a 5G roaming agreement exists, and no 4G roaming; e.g., in IoT use cases or with specific 5G QoS criteria are used that cannot be met in 4G. The AMF can prevent such handover attempts by including RAT (Radio Access Technology) and Core Network Type restrictions in the Mobility Restriction List to NG-RAN.

Note: Handover procedures between 5GS and EPS using the N26 interfaces are specified in 3GPP TS.23.502 [2], Section 4.11.1.2.

5.4 Handover and access restriction between 5GC and EPC

Interworking between EPC and 5GC been specified by 3GPP in 3GPP TS 23.501 [1] with system interworking, covering Handover specified in 3GPP TS 23.502, Section 4.11.2 [2].

5.4.1.1 Mobility Restriction for 5GC from HSS

The UE’s subscription in the HSS may include access restriction for NR in 5GS and restriction for Core Network Type (5GC). If so, the HSS provides these restrictions to the MME. The MME may also, based on local policy, locally restrict accesses. The MME includes these restrictions in the Handover Restriction List to the E-UTRAN. The MME and E-UTRAN use these restrictions to determine if mobility of the UE to 5GC or NR connected to 5GS should be permitted. This way a UE roaming in a VPLMN that utilises 5GC will not be permitted to handover to NR connected to 5GC.

5.4.1.2 Mobility Restriction for EPC from UDM

The UE’s subscription in the UDM may include access restriction for E-UTRAN in EPS and restriction for Core Network Type (EPC). If so, the UDM provides these restrictions to the AMF. AMF may also, based on local policy, locally restrict accesses. The AMF includes these restrictions in the Mobility Restriction List to the NG-RAN. The AMF and NG-RAN use these restrictions to determine if mobility of the UE to EPS or E-UTRAN connected to EPC should be permitted. This way a UE roaming in a VPLMN that utilises EPC will not be permitted to handover to E-UTRAN connected to EPC.

5.4.2 Handover and access restriction between 5GC and Untrusted non-3GPP access

6 Technical Requirements and Recommendations for Services

6.1 Network Slicing

A 5GS UE and 5GC will support network slicing. When a UE registers, it will request NSSAI to the VPLMN, which contains zero or up to eight S-NSSAI. The Subscription information...
shall contain one or more S-NSSAI’s. Network slicing and use of S-NSSAI is described in [1] section 5.15.

Three standardized Service Slice Types (SST) have been specified by 3GPP as shown below in Table 2.

<table>
<thead>
<tr>
<th>Slice/Service type</th>
<th>SST value</th>
<th>Characteristics</th>
</tr>
</thead>
<tbody>
<tr>
<td>eMBB</td>
<td>1</td>
<td>Slice suitable for the handling of 5G enhanced Mobile Broadband</td>
</tr>
<tr>
<td>URLLC</td>
<td>2</td>
<td>Slice suitable for the handling of ultra-reliable low latency communications</td>
</tr>
<tr>
<td>MIoT</td>
<td>3</td>
<td>Slice suitable for handling of massive IoT</td>
</tr>
</tbody>
</table>

**Table 2 3GPP Standardised SST values**

The SST field may have standardized or non-standardized values, with 0-127 allocated to standard value types, and 128-255 allocated to operator specific SST’s.

The GSMA PRD NG.116 provides a standardised view on how a Generic Slice Template (GST) can be used. The GST provides the template for which slice attributes that characterise a network slice can be applied to. A GST can be filled with values that create a NEST (NEtwork Slice Type), which is a slice for a particular Use Case that may be supported by the roaming PLMN operators.

### 6.2 UE support of network slicing when roaming

As stated in 3GPP TS 23.501 [1] Section 5.15.6; if the UE only uses standard S-NSSAI values, then the same S-NSSAI values can be used in the VPLMN as in the HPLMN. If the VPLMN and the HPLMN have an agreement to support non-standard S-NSSAI values in the VPLMN, the NSSF of the VPLMN maps the Subscribed S-NSSAI values (provided by the HPLMN) to the respective S-NSSAI values to be used in the VPLMN, during the registration procedure, and informs the UE about the mapped S-NSSAI values. The UE provides to the network the S-NSSAI values provided by the HPLMN and, if available, the mapped S-NSSAI values provided by the VPLMN during registration and PDU session establishment procedure.

#### 6.2.1 5GC support of network slicing when roaming

The UDM in the HPLMN will contain inside the Subscription Information the Subscribed S-NSSAI’s. When roaming the UDM shall provide to the VPLMN only the S-NSSAI(s) the HPLMN allows for the UE in the VPLMN. i.e. this may be a sub-set of multiple S-NSSAI(s).

When the UDM updates the Subscribed S-NSSAI(s) to the serving VPLMN AMF, e.g. during registration procedure, the AMF itself AMF by interacting with the

- Configured NSSAI and, if needed, the mapping to the Subscribed S-NSSAI(s)
- Allowed NSSAI and, if needed, the mapping to the Subscribed S-NSSAI(s).
- rejected S-NSSAI(s)

The serving AMF then updates the UE with the above information.
It is recommended that the S-NSSAI with eMBB [SST value 1] be supported for roaming, and be the minimum in Subscribed NSSAI in UDM for subscriptions using e.g. Internet access and IMS services. Other S-NSSAI can be provided as Subscribed NSSAI if required.

6.3 Voice and Short Message Service (SMS)

It is recommended that for IMS voice, video and SMS services, are on the same network slice to avoid multiple IMS registrations on different network slices for these services, see also GSMA PRD NG.114 [20]. It is recommended for roaming to, make use of the S-NSSAI with eMBB SST value 1 exclusively GSMA PRD NG.114 [20] provides the guideline on the IMS profile for voice, video and SMS over 5GS.

7 Other Technical Requirements and Recommendations

7.1 Access Control

Without an explicit roaming agreement from the HPMN, the VPMN must block the access of inbound roamers onto their 5G-NR access network. This is compulsory to ensure roamers will not experience any service disruption because the necessary technical requirements have not been implemented and tested within the HPMN.

7.1.1 Access Control in the VPMN

The AMF in the VPMN shall implement the same sort of access control feature that exist in EPC MME, and 2G / 3G Core, MSC and SGSN. One mechanism to achieve this is based on the MCC and MNC range information inside of the Subscription Concealed Identifier, SUCI (based on IMSI). Using this mechanism, the subscriber is either rejected (with the appropriate reject cause as defined in 3GPP TS 24.501 [28]) or allowed to “attach” and perform the subsequent Tracking Area Update procedures.

If the procedure is to be rejected, then the appropriate error cause is:

- Cause #15 (no suitable cells in Tracking Area) if the VPMN already has a Roaming Agreement with the HPMN covering other Radio Access Technologies (RATs), it forces the UE to reselect another RAT in the same PMN
- Cause #11 (PLMN Not Allowed) if the VPMN has no roaming agreement with the HPMN. It forces the UE to perform a PMN reselection. UE shall store the PMN identity in the "forbidden PLMN list" in the USIM (Universal Subscriber Identity Module) and the UE shall no more attempt to select this PMN. Cause #13 may also be used (to avoid permanent storage of PMN in the Forbidden PMN file in the USIM).

IMS Voice over PS Session support indication shall be sent to a roaming UE, only if there is an IMS voice roaming agreement between the HPMN and VPMN in place.

7.1.2 Access Control in the HPMN

If the VPMN does not implement the requirements in the previous section, then the HPMN can implement its own access control feature in the UDM to protect its subscribers.

If the HPMN already has a Roaming Agreement with the VPMN covering other RAT access technologies then the reject indication sent by the UDM back to the AMF in the
Nudm_UECM_Registration response HTTP status code “403 Forbidden”, will contain the additional error information in the response body, “ProblemDetails” element. The “ProblemDetails” Data type will use the “cause” attribute – RAT_NOT_ALLOWED. Figure 9 below illustrates the AMF registration service operation.

![Figure 9 AMF registering for 3GPP access](image)

The AMF must then map the RAT_NOT_ALLOWED cause from the UDM into the cause #15 (no suitable cells in Tracking Area) to send to the UE. The AMF should not map RAT_NOT_ALLOWED into cause #12 (Tracking area not allowed) or #13 (Roaming not allowed in this tracking area) or #11 (PLMN not allowed.)

### 7.2 IP Addressing

The 5GS has significant differences to GPRS (2G), 3G and LTE (4G) networks that push the drive to use of IPv6 as much as possible. Reasons such as:

- Integration with broadband [fixed] network and control planes
- Use of non-3GPP access, and more small cell endpoints
- Network slices across Access and Core networks
- Hosting of functions with NFV / cloud-based infrastructure
- Support of Mobile Edge Compute (MEC) and 3rd party access
- Massive IoT volumes for UE

Network operators could have insufficient IPv4 resources, thus the 5G UE and 5G network must support the use of IPv6 as the PDU session type. For the purpose of supporting the service or feature provided through the DN that requires native IPv4 connectivity, use of IPv4 and IPv4v6 should be considered.

### 7.2.1 UE Addressing

Every 5G capable UE using the IPv6 or IPv4v6 is allocated one or more IP addresses. One per PDU session as a minimum.

Section 5.8.2.2. of 3GPP TS 23. 501 [1] provides information on UE IP Address Management. IPv6 and IPv4v6 session types are allowed. PDU Session Type IPv6 only is recommended.
7.2.1.1 General
Every 5G capable UE using the IPv4, IPv6, or IPv4v6 is allocated one or more IP addresses. One per PDU session as a minimum.

Section 5.8.2.2. of 3GPP TS 23.501 [1] provides information on UE IP Address Management. IPv4, IPv6 and IPv4v6 session types are allowed. Other non-IP PDU Session types, i.e. Ethernet and Unstructured, are also allowed. PDU Session Type is based on the request sent by UE and the support and any policy in the network, where SMF decides whether to accept, partially accept, or decline the request from UE.

7.2.1.2 PDU Session Type Requested by UE
UE must request using PDU Session Type as specified in section 5.8.2.2.1 of 3GPP TS 23.501 [1].

7.2.1.3 PDU Session Type Accepted by the Network
SMF must select the PDU Session Type to be used as specified in section 5.8.2.2 of 3GPP TS 23.501 [1], based on UE’s request, DNN configuration, local policy at SMF, and/or IP version supported by the DNN.

For Home Routed Roaming, the PDU Session Type is decided by HPMN, i.e. by the H-SMF, and as the VPMN, i.e. V-SMF, will only transparently forward the requested PDU Session Type to HPMN, decision of the accepted PDU Session Type is solely dependent on the policy at HPMN.

For Local Breakout Roaming, the PDU Session Type is decided by VPMN, i.e. by the SMF in VPMN serving the inbound roamer, and operators must negotiate on the PDU Session Type to be accepted. It is recommended that PDU Session "IPv6" is supported at minimum for the reason as described in Section 6.2. Other PDU Session Types may be supported for the purpose of supporting legacy services based on bilateral negotiation between the VPMN and HPMN.

7.2.2 5GC Network Function Addressing
The 5GC supports a PDU Connectivity Service, i.e. a service that provides exchange of PDUs between a UE and a data network identified by a DNN. The PDU Connectivity Service is supported via PDU Sessions that are established upon request from the UE.

Section 5.6.1 of 3GPP 23.501 [1] states that the following PDU Session types are defined: IPv4, IPv6, IPv4v6, Ethernet, Unstructured.

It is recommended that routing across PLMN NF services makes use of IPv6 only.

7.2.2.1 Fully Qualified Domain Names (FQDNs)
Section 6.1.4.3 of 3GPP TS 29.500 [20] specifies how HTTP/2 request messages are routed between PLMNs, where the correct target NF service should be reached. Where the target URI authority designates an origin server not in the same PLMN as the client, the “authority” HTTP/2 pseudo-header shall contain the FQDN including the PLMN ID.
The format of the FQDN of the target NF service is specified in 3GPP TS 23.003 [28] Section 28.5. For HTTP/2 request messages to a NF service in different PLMN, the FQDN of the target NF shall have the Home Domain as the trailing part – i.e.

- 5gc.mnc<MNC>.mcc<MCC>.3gppnetwork.org

### 7.3 APN for IMS based services

Refer to GSMA PRD IR.88 [3], Section 6.3.

### 7.4 Emergency PDN Session

### 7.5 Security

Ensuring adequate security levels is not just a matter of deploying the right technology in the right place. It is critical that proper procedures are adequately defined and continuously adhered to throughout the entire security chain, particularly at an operational level. Security cannot be achieved by just one stakeholder in a network, it requires that every single stakeholder fulfils their part of the requirements.

Due to interconnect and roaming, the inner PLMN is exposed to other networks. Consequently, measures to securely allow partners to interconnect in a controlled way have to be deployed, without revealing confidential information or facilitating fraud/abuse. Furthermore, the mobile ecosystem is changing. There is an increasing demand on security by the public and by regulators. With the 5G standard, 3GPP addresses these demands by introducing new security controls and secure inter-operator communication, all of which are introduced in this document and in particular in this section.

This section covers all aspects relevant for deploying and operating 5G roaming securely. Aspects, such as security controls at the network edge, secure communication, key management and protection policy exchange are covered.

PLMN operators and IPX Providers are advised to adhere to the recommendations which are given in this section.

#### 7.5.1 Fundamentals

Security requires a comprehensive approach. There is the need for all PLMN operators and IPX Providers to:

- Have a secure network design that isolates all parts of the network that need not to be reached from the outside;
- Secure all entry points into their networks at the edge;
- Deploy secure communication between PLMNs;
- Introduce, apply and maintain security procedures.

A secure network design guarantees that the impact of a failure or an attack is limited, as it cannot spread to other parts of the network. As a concrete measure, PLMN operators should only expose the network functions to the IPX Network that are to be reachable by partners. More on network design and fundamental network security aspects can be found in the binding GSMA PRD IR.77 [32].
At the network edge, all entry points should be configured securely, all incoming traffic should be validated and discarded if unwanted. Security is to be applied on all layers. It is good security practice to filter traffic on IP level and to perform DoS (denial of service) protection at the border gateway (BG) as the outermost device, followed by a firewall that filters on transport and application layer. For signalling traffic, this firewall is the SEPP. For user plane traffic, it is the UPF/UP gateway. For fundamentals on network edge security on network layer and transport layer, the reader is referred to the binding GSMA PRD IR.77 [32]. Application layer aspects of 5G are covered in this document and in GSMA PRD FS.21 [30], an overview of and an introduction into signalling security is provided.

Secure communication for 5GS between PLMNs is defined by N32 security and N9 security, as specified by 3GPP in TS 33.501 [19], and in this section.

A variety of security procedures for preparing roaming agreements, deploying and configuring network equipment, maintaining roaming connections and network equipment, dealing with faults, attacks and software upgrades are to be introduced and applied. The binding GSMA PRD IR.77 [32] covers general aspects and this document deals with the specifics of 5G roaming security, in particular Protection Policy definition, agreement and exchange and cryptographic key exchange.

The documents referenced above are applicable and important to the same extent as this section is applicable and important to PLMN operators and IPX Providers.

### 7.5.2 5G Roaming Security Architecture Overview

5G roaming security architecture consists of the Security Edge Protection Proxies (SEPPs) that communicate over the N32 interface and the respective Protection Policies for the SEPPs. The Security Edge Protection Proxy (SEPP) has been introduced in 3GPP TS 33.501 [19] 5GS security architecture. Details to the interface between 2 SEPPs via Inter PLMN N32 interface are provided in clause 3.2. Operators manually provision SEPPs with a Protection Policy based on bilateral agreements as elaborated in detail in clause 6.5.6. Protection policies can be validated via N32-c, which is protected by TLS.

In summary, the SEPP is a non-transparent proxy to allow secure communication between service-consuming and a service-producing NFs in different PLMNs. The SEPPs sitting at the perimeter of each network and enforce via N32 interface the protection policies ensuring integrity and confidentiality protection for those elements to be protected and defining, which parts are allowed to be modified by an IPX provider sitting between the SEPPs.

The functionality of the SEPP includes message filtering and policing on inter-PLMN control plane interfaces as well as topology hiding. To achieve this, the SEPP performs application layer security by PRINS (PRotocol for N32 INterconnect Security) on all HTTP messages before they are sent externally over the roaming interface.

The SEPP applies its functionality to every Control Plane message in inter-PLMN signalling, acting as a service relay between the actual Service Producer and the actual Service Consumer. For both Service Producer and Consumer, the result of the service relaying is equivalent to a direct service interaction.

The IPX HTTP Proxy is out of scope in 3GPP. It allows the IPX service provider to modify information elements received by the SEPP in a controlled way. For details see clause 3.2.1.
7.5.3 5G Roaming Control Plane Security

In support of 5G roaming, operators will need to filter and control their exchange of HTTP/2 messages with the SEPPs of their roaming partners. In addition to the TCP/TLS/IP lower layer filter actions as in section 6.5..., the 5G roaming filter and control actions especially refer to application layer security (ALS as defined in 3GPP TS 33.501 [19]) controls and cross-layer checks like:

- To validate if the 5G roaming control information received via the N32 interface in one or more JSON objects is allowed, correct and plausible for this end-user
- Idem, to check if the 5G roaming control information in one or more JSON objects is allowed, correct and plausible to be received from this home or visiting network

To verify if information in a JSON object matches with the IP address on the IP layer by performing cross-layer information checking.

These checks and supplementary balancing actions (like throttling and traffic policies) are only possible by the SEPP to decide if the HTTP/2 message can be forwarded to the final destination in the receiving network, or not.

In addition, to investigate the authenticity of the sending roaming partner, to validate and screen the control actions of the messages via the API interface.

The filtering actions are recommended to work on the basis of a "White-List" principle (i.e. only pass messages that meet given conditions) similarly as specified for LTE with the Diameter firewall guidelines in GSMA FS.19 Annex B.

Please note that the subsequent sections only provide high-level introduction to the security aspects of the ALS signalling application protocols. Further details can be found in:

- GSMA FS.17 with detailed guidelines for both the HTTP/2 security aspects and the JSON security aspects
- GSMA FS.21 with proposed sets of RFI/RFQ requirements for the 5GS functional elements and the related implementation and testing aspects.

7.5.3.1 HTTP/2 Security

7.5.3.2 JSON Security

7.5.3.3 API Security

7.5.4 5G Roaming User Plane Security

In support of 5G roaming, operators will need to filter and control their exchange of GTP-U messages over the N9 reference point with their roaming partners.

In the 5GS security architecture the roaming control messages are exchanged between SEPPs over the N32 interface with a similar working as in LTE with the filtering of GTP-C roaming control messages as specified in GSMA PRD FS.20. However, in 5G the related transfer of GTP-U user control message is not altered and will still follow the N9 interface as in LTE.
In this context, a filtering solution will be needed that determines if the GTP-U traffic is linked to a corresponding N32 session. This way of working is still under consideration in 3GPP as new a new feature for Release 16 and likely related to a “UP GW Function” on the N9 interface as in TS 33.885 section 4.1.17. Further details will be provided with as soon as SA2 completed their work.

In addition, relevant aspects may be considered as specified in GSMA PRD IR.88 [3] section 6.5.1 for LTE.

7.5.5 Key Management for 5G Roaming Security

Cryptographic key material is required

For Rel. 15 only manual bilateral exchange of key between roaming partners is defined

Operators need to:

- Establish a trusted source in their organisation that produces and distributes keys
- Communicate the trusted source to their roaming partners
- Produce and exchange keys in a secure way
- Agree on crypto algorithms, keying measures, procedures and exchange channels
- Forward keys/certificates of their IPX Providers in a secure way

Operators are recommended to establish a PKI (Public Key Infrastructure) and exchange certificates rather than individual keys

Operators are recommended to monitor certificate lifetimes to exchange new keys before the current keys expire

This section is limited to explanations on what is to be done technically. However, this is explained in another PRD that is being written by FASG DESS (Fraud and Security Group). And a reference will be added to this document as soon as it is available.

7.5.6 Protection Policy Agreement and Exchange

- Technical descriptions on creating and handling protection policies.
- Create/handle Modification Policy
- Create/handle Encryption Policy
- Technical aspects of exchanging policies
- Technical aspects of keeping policies up-to-date

7.5.7 Preparatory Steps per 5G Roaming Relation

- Agree on and exchange protection policies and keys as described above.
- Section covers the procedures and organisational framework to follow the technical guidelines in the previous two subsections.
- Establish communication channels to easily deploy policy and key updates.

7.5.8 Error Handling

For 5G roaming, the SEPP handles the security errors in the following cases:
• Errors in verifying the integrity protection of the N32-f message: if the receiving SEPP is not able to verify the integrity protection of the message, the receiving SEPP responds an error signalling message to the initiating SEPP with an appropriate status code (as specified in 3GPP TS 29.573 [10]).

• Errors in decrypting the JWE ciphertext in the N32-f message: if the receiving SEPP is not able to decrypt the JWE ciphertext in the N32-f message, the receiving SEPP responds an error signalling message to the initiating SEPP with an appropriate status code (as specified in 3GPP TS 29.573 [10]).

• Errors in checking integrity of the JSON object in the N32-f message: if the receiving SEPP fails to check the integrity of the JSON object in the N32-f message, the receiving SEPP responds an error signalling message to the initiating SEPP with an appropriate status code (as specified in 3GPP TS 29.573 [10]).

• Errors in verifying the JWS signatures added by the intermediaries (i.e. IPX provider): if the receiving SEPP fails to verify the JWS signatures added by the intermediaries, the receiving SEPP responds an error signalling message to the initiating SEPP with an appropriate status code (as specified in 3GPP TS 29.573 [10]).

• Errors in verifying the PLMN-ID contained in the N32-f message: if the receiving SEPP verifies that the PLMN-ID contained in the incoming N32-f message mismatch the PLMN-ID in the related N32-f context, the receiving SEPP responds an error signalling message to the sending SEPP with "403 Forbidden" status code with the application specific cause set as "PLMNID_MISMATCH" (as specified in 3GPP TS 29.573 [10]).

7.5.9 Issue Tracking and Incident Handling

• Forward issues to involved partners.
• Agree on machine readable data structure of issues raised towards stakeholders.
• Agree on procedures for issue tracking and how to establish them across stakeholders.

7.6 Steering of Roaming using 5G SBA

3GPP have specified a new method to enable Steering of Roaming when using 5G-NR and the 5GC. Details are specified in GSMA PRD IR.73 [31].

8 Technical Requirements for QoS support

8.1 QoS Parameters definition

TS 23.501 – 5.7

8.2 QoS management

8.3 QoS control

9 Testing Framework

IREG test cases for 5GS SBA roaming will be described in a future PRD.
